Peer Support and Trauma Recovery

Peer support is becoming an important strategy to help survivors of war-related violence recover from psychological trauma. After a short training in counseling techniques, peer-support workers seek out trauma survivors in the community and help them reintegrate into society, find work, engage in sports and come to terms with their traumatic memories. Peer-support programs incur costs related to transportation and communication, but support groups may recover some costs through income-generating projects.

F

or most people who survive injuries from landmines or other explosive remnants of war, friends and family can significantly aid in the recovery process. Survivors rarely recover in isolation, support from concerned people in the survivor’s life is often the single most crucial element in the period of healing.

Survivors call upon their own inner resources to tolerate physical pain, mental anguish, flashbacks, nightmares, fear, difficulty with daily activities, loss of employment or school interruption, as well as stigma, discrimination and the humiliation of depending on others for assistance. Yet emotional support, companionship, sensitivity and affection are natural human responses and, in this painful time, often make the difference between hope and the desire to move forward and recreate a “normal” life.3

Some organizations providing victim assistance for survivors recognize the power of psychosocial support and incorporate it into their programs. In particular, many victim-assistance programs—survivors similar in age, gender and social background, and especially those who share a history of trauma survival. Peer support has become a standard way to help survivors recover from psychological trauma. Peer-support workers seek survivors as either one-to-one individual counseling or in group sessions where all members are survivors. Peer-support workers receive some training on how to:• Provide effective counseling• Deal with suicidal behavior and substance abuse• Help survivors obtain professional services, such as dealing with health problems, starting a business, finding work or applying for financial assistance

Landmine Survivors Network established peer-support programs in 12 countries before closing in 2010. Peer support is offered to survivors as either one-to-one individual counseling or in group sessions where all members are survivors. Peer-support workers receive some training on how to: • Provide effective counseling • Deal with suicidal behavior and substance abuse • Help survivors obtain professional services, such as dealing with health problems, starting a business, finding work or applying for financial assistance

Because peer-support workers are survivors, some of their training includes how to deal with their own feelings of fear, anger and grief, which is important in coping with emotions that other survivors’ stories may trigger.

Peer-support workers are sometimes referred to as “outreach workers” because they seek out survivors in the community who may not have received treatment or attention for their psychological trauma. Trauma survivors may isolate themselves and avoid social contact, remaining bitter and depressed for years. By visiting a survivor in his or her home, a skilled peer-support worker can encourage a survivor to return to the social network, which improves self-esteem, increases problem-solving capabilities and reduces the incidence of suicide.

Once survivors are comfortable in a social setting, they usually benefit from a survivor-support group. Support groups meet for a variety of reasons, not always overtly related to trauma recovery but frequently for more practical activities such as income generation, entertainment or sports. In the midst of these events, peer support takes place and survivors benefit from contributing...
to a group effort. Support groups expose survivors to others who are in different stages of recovery and are in the process of overcoming various types of trauma. Researchers and clinicians feel there is a solid theoretical basis for peer-support’s effectiveness as a therapeutic method. When someone recognized as a “peer” provides support to a survivor, a variety of psychosocial processes come into play, as described by Phyllis Solomon.

Social support consists of positive psychosocial interactions in which there is mutual trust and concern. Healthy relationships contribute to positive adjustment and help survivors deal with stress and challenges through emotional support (esteem, attachment and reassurance), instrumental support (material goods and services) and information support (advise, guidance and feedback).

Experiential knowledge comes from dealing with a particular set of challenges such as substance abuse, a physical disability, a chronic illness or surviving a traumatic event such as military combat, a natural disaster, domestic violence, sexual abuse or imprisonment. When shared, experiential knowledge helps a survivor solve problems and improves a survivor’s quality of life.

Social learning theory postulates that peers, because they have undergone and survived relevant experiences, are more credible role models for others. When survivors interact with peers who cope successfully with stress, difficulties or illness, they are more likely to exhibit positive behavior changes.

Social comparison theory suggests people are constantly comparing themselves to those around them. They are more comfortable with others who share common characteristics with them, which helps them establish a sense of normalcy. Interacting with others who are perceived to be better than them gives them a sense of optimism and something to strive toward. Helping others, they consider to be struggling or in need, enhances people’s own sense of self-worth.

The helper-therapy principle proposes four main benefits for those who provide peer support. As a result of making an impact on another person’s life, the “helper” has an increased sense of interpersonal competence, experiences the reward of positive exchange, learns useful skills and receives social approval from the person they help and others.

Establishing New Peer-Support Programs

In spite of peer support’s effectiveness in promoting recovery from trauma of survivors and of those who help them, peer-support programs have drawbacks. Individual one-to-one peer support is expensive to implement because peer-support workers need transportation to visit survivors in their homes, and this may require programs to cover the costs of public transportation, or provide peer-support workers with a bicycle or a motor scooter and associated expenses such as fuel. Many peer-support programs pay for or subsidize mobile phones for peer-support workers so they can stay in contact with survivors as well as with their own supervisors and can help survivors set up appointments, or network for jobs and other opportunities.

Peer-support workers are sometimes volunteers, but many programs pay them salaries commensurate with their experience and training. Supervisors (usually social workers or program managers) are also necessary, and there may be a need to hire specialists in employment opportunity and advocacy. Peer-support groups can have better than one-to-one form of support, but costs are still associated with transporting survivors to group meetings, except in very small communities. Support groups may request contributions from members in order to cover costs, or they may organize income-generating projects such as vegetable gardens, theater or crafts. In some cases peer-support groups for landmine survivors have grown into independent nongovernmental organizations, as in Bosnia and Herzegovinā and El Salvador. Lastly, some psychotherapists argue that support from a peer with only brief training in counseling may be more helpful to survivors suffering from severe psychological trauma. Special training is needed to help survivors deal with suicidal depression, hallucinations, drug and alcohol abuse, and flashbacks. Inappropriate counseling has the potential to worsen some conditions or at the very least, interfere with the healing process. In addition, peer-support workers can experience “vicarious trauma” from hearing survivors’ trauma stories.

Although there is some risk, most peer-support programs have access to professional psychotherapists to whom they can refer survivors with problems that are too severe for the peer-support worker to handle. Peer support is never considered to be a substitute for psychotherapy, but it is a useful supplement, especially in areas where health-care services are sparse. The training of peer-support workers is growing more sophisticated and now emphasizes the limits of peer support, as well as its benefits.

Conclusion

Trauma specialists worldwide recognize that most survivors are capable of full recovery from psychological trauma under the right circumstances and that an accepting, supportive social environment is a key factor in preventing long-term psychological dysfunction.

Peer support encourages survivors to provide that supportive network for the trauma-stricken, and it can often help survivors recover quickly without seeking help outside the community. Peer-support programs for trauma survivors can supplement thinly-stretched mental health services in post-conflict settings and promote vital social reconstruction following a war.
